Bivariate Model

Assumptions: $\mathbb{E}[u_i] = 0$, $\text{Var}[u_i] = \sigma^2$, $\mathbb{E}[u_i, u_j] = 0$ for $i \neq j$,
 x_i nonstochastic

From $y_i = \beta_1 + \beta_2 x_i + u_i$, want to minimize

$$RSS = \sum_{i=1}^N (y_i - \beta_1 - \beta_2 x_i)^2$$

$$\text{FOCs: } \frac{\partial RSS}{\partial \beta_1} = -2 \sum_{i=1}^N \tilde{u}_i = 0, \quad \frac{\partial RSS}{\partial \beta_2} = -2 \sum_{i=1}^N x_i \tilde{u}_i = 0$$

$$\text{From first FOC: } \hat{\beta}_1 = \sum_{i=1}^N \frac{y_i}{N} + \hat{\beta}_2 \sum_{i=1}^N \frac{x_i}{N} = \bar{y} - \hat{\beta}_2 \bar{x}$$

$$\text{Substituting into second FOC: } \hat{\beta}_2 = \frac{\sum_{i=1}^N (y_i - \bar{y}) \sum_{i=1}^N (x_i - \bar{x})}{\sum_{i=1}^N (x_i - \bar{x})^2}$$

The Three Classical Tests of MLE

Gauss-Markov Assumptions

Given a linear model, $\hat{\beta}_{OLS}$ is a consistent estimator of β if

- (1) No perfect collinearity in X (drop redundant observations)
- (2) No selection bias (a representative sample)
- (3) $\mathbb{E}[u] = 0$ (guaranteed if we include an intercept)
- (4) $\mathbb{E}[Xu] = 0$ (unbiased if $\mathbb{E}[u|X] = 0$)

$$(3) + (4) \Rightarrow \text{Var}[\varepsilon] = \sigma^2 I_N.$$

$$(2) \Rightarrow \mathbb{E}[\varepsilon|x] = \mathbb{E}[\varepsilon] = 0 \text{ and } \text{Var}[\varepsilon|x] = \text{Var}[\varepsilon].$$

Assumption (4) is the focus of much attention, as we will discuss. But even without (4), we can always interpret $\hat{\beta}_{OLS}$ as summaries of correlations in the data, rather than as parameter estimates.

MLE Properties

The Three Classical Tests of MLE

Gauss-Markov Assumptions

Unbiasedness and Variance

Unbiasedness:

$$b = \beta + (x'x)^{-1}x'\varepsilon$$

$$\mathbb{E}[b|x] = \beta + \mathbb{E}[(x'x)^{-1}x'\varepsilon|x] \quad (1)$$

$$\stackrel{\text{by 2}}{=} \beta + \mathbb{E}[(x'x)^{-1}x'|x]\mathbb{E}[\varepsilon|x] \quad (2)$$

$$\stackrel{\text{by 1}}{=} \beta \quad (3)$$

Variance:

$$\text{Var}[b|x] = \mathbb{E}[(b - \mathbb{E}[b])(b - \mathbb{E}[b])'|x] \quad (4)$$

$$= \mathbb{E}[(b - \beta)(b - \beta)'|x] \text{ from unbiasedness} \quad (5)$$

$$= \mathbb{E}[(x'x)^{-1}x'\varepsilon\varepsilon'x(x'x)^{-1}|x] \quad (6)$$

$$= (x'x)^{-1}x'(\sigma^2 I_N)x(x'x)^{-1} \text{ by 3 and 4} \quad (7)$$

$$= \sigma^2(x'x)^{-1} \quad (8)$$

Maximum Likelihood Estimation

Introduction

MLE Properties

The Three Classical Tests of MLE

Gauss-Markov Assumptions

DF Adjustment, Consistency, and Asymptotics

Significance Tests:

Assumption 5: $\varepsilon \sim N(0, \sigma^2 I_N) \Rightarrow b \sim N(\beta, \sigma^2(x'x)^{-1})$

$$\Rightarrow \text{unbiased estimator of } \sigma^2 : S^2 = \frac{1}{N-k} \sum_{i=1}^N \varepsilon_i^2$$

Consistency:

Plim = β as $N \rightarrow \infty$ (Asymptotics)

Assumption 6: $\frac{1}{N} \sum_{i=1}^N x_i x_i'$ converges to finite nonsingular matrix Σ_{xx} .

Assumption 7: $\mathbb{E}[x_i \varepsilon_i] = 0$

Distribution:

As $N \rightarrow \infty$, $\sqrt{N}(b - \beta) \rightarrow N(0, \sigma^2 \Sigma_{xx}^{-1})$

Approximate in finite samples $b \sim N(\beta, S^2(x'x)^{-1})$

Frisch-Waugh(-Lovell) Theorem

Partitioned Regressions

$$y = x_1\beta_1 + x_2\beta_2 + \varepsilon \quad \text{or} \quad \begin{bmatrix} x_1 & x_2 \\ x_1 & x_2 \end{bmatrix} \begin{bmatrix} \hat{\beta}_1 \\ \hat{\beta}_2 \end{bmatrix} + \begin{bmatrix} \varepsilon \\ \varepsilon \end{bmatrix} = \begin{bmatrix} y \\ y \end{bmatrix}$$

Premultiply by x_1' and x_2' yo get rid of ε .

Premultiply lower equation by $(x_1'x_2)(x_2'x_2)^{-1}$ to get

$$(x_1'x_2)(x_2'x_2)^{-1}(x_2'x_1)\hat{\beta}_1 + (x_1'x_2)\hat{\beta}_2 = (x_1'x_2)(x_2'x_2)^{-1}x_2'y$$

Subtract this from upper equation to get rid of $\hat{\beta}_2$ and define

$$P_2 = x_2(x_2'x_2)^{-1}.$$

$$\hat{\beta}_1^{OLS} = [x_1'(I - P_2)x_1]^{-1}x_1'(I - P_2)y$$

So, we purged x_1 off its correlation with x_2 . The regression "controls" for x_2 .

Frisch-Waugh(-Lovell) Theorem

Omitted Variable Bias

What did we do?

1. Regress x_1 on x_2 .
2. Residual matrix $E_{1,2} = (I - P_2)x_1$.
3. $y \sim E_{1,2}$

Another way to see this:

$$\text{Assume } \mathbb{E}[x_2|x_1] = \pi x_1$$

$$y = \beta_1 x_1 + (\beta_2 x_2 + \varepsilon)$$

$$\mathbb{E}[y|x_1] = \beta_1 x_1 + \mathbb{E}[\beta_2 x_2|x_1] + \mathbb{E}[\varepsilon|x_1] = \beta_1 x_1 + \beta_2 \pi x_1$$

The multivariate regression decomposes the overall effect of changes in x_1 into a direct effect, β_1 , and an indirect effect associated with changes in x_2 , $\beta_2 \pi$.

In contrast, a univariate regression would have given the overall effect

$$\hat{\beta}_1^* = \hat{\beta}_1 + \pi \hat{\beta}_2.$$

Measurement Error

Also called Errors-in-the-variables (EIV), Attenuation Bias, and Asymptotic Bias

Measurement error in dependent variable not a problem for OLS consistency or validity, but problematic if in independent variable.

$$y_i = \beta x_i^* + \varepsilon_i$$

But we only observe $x_i = x_i^* + v_i$, $v_i \sim N(0, \sigma_v^2)$.

Errors flatten out OLS line due to scattered point estimates.

$$\begin{aligned} Plim(b) &= plim \left(\frac{\sum x_i y_i / n}{\sum x_i^2 / n} \right) = \frac{Cov(x^* + v, \beta x^* + \varepsilon)}{Var(x)} \\ &= \beta \cdot \frac{\sigma_{x^*}^2}{\sigma_{x^*}^2 + \sigma_v^2} = \beta \cdot \frac{1}{1 + \frac{\sigma_v^2}{\sigma_{x^*}^2}} \end{aligned}$$

Introduction

MLE Properties

The Three Classical Tests of MLE

Measurement Error

Alternative Intro

We observe $x_i = x_i^* + v_i$ where x_i^* is true value

$$\begin{aligned}y_i &= \alpha + \beta x_i^* + \varepsilon_i \\ &= \alpha + \beta(x_i - v_i) + \varepsilon_i \\ &= \alpha + \beta x_i + (\varepsilon_i - \beta v_i) \\ &= \alpha + \beta x_i + u_i\end{aligned}$$

Both x_i and u_i depend on v_i , so correlated \Rightarrow OLS estimation downward biased.

Measurement error in y_i increase variance in error term but does not cause endogeneity.

$$y = x_1\beta_1^* + v \quad \text{and} \quad y = x_1\beta_1 + x_2\beta_2 + \varepsilon$$

$$\begin{aligned}\beta_2 &= (x_1'x_1)^{-1}x_1'(y - x_2\beta_2) \\ &= (x_1'x_1)^{-1}x_1'y - (x_1'x_1)^{-1}x_1'x_2\beta_2 \\ &= \beta_1^* - (x_1'x_1)^{-1}x_1'x_2\beta_2\end{aligned}$$

$$\Rightarrow \beta_1^* = \beta_1 + G\beta_2 \Rightarrow \text{Asymptotic bias (unless } G = 0 \text{ or } \beta_2 = 0)$$

- ▶ No OVB if $\text{corr}(x_1, x_2) = 0$.
- ▶ OVB does not cause $\text{corr}(x_1, v) \neq 0$ as $\mathbb{E}[v|x_1] = 0$ in short regression.
- ▶ But if OVB x_1 corr to composite error term $u = x_2\beta_2 + \varepsilon$.
- ▶ If you do not control for x_2 , you assume that x_2 varies with changes in x_1 .

Generalized Least Squares (GLS)

Cholesky Decomposition

To demonstrate properties of GLS transform to CLRM and show that BLUE.

1. Transform

Cholesky Factorization: $D = (L')^{-1}L^{-1} \Rightarrow L'DL = I_t$, given D symm,
pos - def

So: $L'y = L'x\beta + L'\varepsilon \Rightarrow y^* + x^*\beta + \varepsilon^* \Rightarrow \text{CLRM}$

2. Show Properties

By Gauss - Markov, $\hat{\beta}_{OLS}^* = (x'^*x^*)^{-1}x'^*y^*$ is BLUE, so

$$\begin{aligned}\hat{\beta}_{GLS} &= (x'LL'x)^{-1}x'LL'y \\ &= (x'D^{-1}x)^{-1}x'D^{-1}y \\ &= (x'(\sigma^2D)^{-1}x)^{-1}x'(\sigma^2D)^{-1}y \\ &= (x'\Sigma^{-1}x)^{-1}x'\Sigma^{-1}y\end{aligned}$$

Note That

$$\begin{aligned}&= (x'\Sigma^{-1}x)^{-1}x'\Sigma^{-1}(x\beta + \varepsilon) \\ &= \beta + (x'\Sigma^{-1}x)^{-1}x'\Sigma^{-1}\varepsilon\end{aligned}$$

Feasible Generalized Least Squares (Feasible GLS)

Often Σ is unknown but $\hat{\Sigma}$ exists.

Sufficient conditions for consistency and asymptotic normality of FGLS:

1. $plim \frac{1}{N} x' \hat{\Sigma}^{-1} x \rightarrow Q_{\Sigma} > 0$.
2. $plim \frac{1}{N} x' \hat{\Sigma}^{-1} \varepsilon \rightarrow 0$

why?

$$\hat{\beta}_{FGLS} = (x' \hat{\Sigma}^{-1} x)^{-1} x' \hat{\Sigma}^{-1} y = \beta + (x' \hat{\Sigma}^{-1} x)^{-1} x' \hat{\Sigma}^{-1} \varepsilon$$

$$Plim(\hat{\beta}_{FGLS} - \beta) = Plim(x' \hat{\Sigma}^{-1} x)^{-1} plim(x' \hat{\Sigma}^{-1} \varepsilon) \rightarrow (Q_{\Sigma})^{-1} \cdot 0 = 0$$

If heteroskedasticity of unknown form, i.e. $\mathbb{E}[\varepsilon_t^2] = \sigma_t^2$ and $\Sigma = \text{diag}(\sigma_t^2)$,

We can estimate $\hat{\sigma}_t^2 = \hat{\varepsilon}_t^2$ from a first - stage regression. But $\hat{\Sigma} \rightarrow \Sigma$.

Note that $\frac{1}{N} x' \hat{\Sigma}^{-1} x = \frac{1}{N} \sum_t \frac{1}{\hat{\sigma}_t^2} x_t x_t'$ where $\hat{\Sigma}$ is $k \times k$ fixed since $N \rightarrow \infty$.

So: $plim \frac{1}{N} x' \hat{\Sigma}^{-1} x \rightarrow Q_{\Sigma} > 0$ and $plim \frac{1}{N} x' \hat{\Sigma}^{-1} \hat{\varepsilon} \rightarrow 0$.

MLE Introduction

Intuition: Find θ that maximizes the likelihood of observations.

$$\max_{\theta} L(\theta; y) = \max_{\theta} \prod_{i=1}^N f(y_i; \theta) \text{ or } \max_{\theta} \log L(\theta; y) = \max_{\theta} \sum_{i=1}^N \log f(y_i; \theta)$$

Efficient score: $S(\theta) = \frac{\partial \log L}{\partial \theta}$. MLE is solution to $S(\hat{\theta}) = 0$.

Example:

$$y_i = \alpha + \beta x_i + \varepsilon_i, \quad \varepsilon_i \sim IN(0, \sigma^2), \quad y_i \sim IN(\alpha + \beta x_i, \sigma^2)$$

$$f(y_i) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp \left[-\frac{1}{2\sigma^2} (y_i - \alpha - \beta x_i)^2 \right]$$

$$\log L(\alpha, \beta, \sigma^2; \text{data}) = \sum_{i=1}^N \left[-\frac{1}{2} \log(2\pi\sigma^2) - \frac{1}{2\sigma^2} (y_i - \alpha - \beta x_i)^2 \right]$$

MLE Introduction

FOC's:

$$[\alpha] \sum_{i=1}^N (y_i - \hat{\alpha} - \hat{\beta}x_i) = 0$$

$$[\beta] \sum_{i=1}^N x_i (y_i - \hat{\alpha} - \hat{\beta}x_i) = 0$$

$$[\sigma^2] \underbrace{N\hat{\sigma}^2}_{\text{not } (N-2)!} = \sum_{i=1}^N (y_i - \hat{\alpha} - \hat{\beta}x_i)^2$$

Plug in $\hat{\sigma}^2$ in $\log L(\alpha, \beta, \sigma^2; \text{data})$ to see maximized $\log L$ is

$$\log L(\hat{\theta}) = \text{constant} - \frac{N}{2} \log \hat{\sigma}^2 = \text{constant} - \frac{N}{2} \log \left(\frac{RSS}{N} \right)$$

$$\text{Individual Score: } S_i(\theta) = \frac{\partial \log L_i(\theta)}{\partial \theta}$$

MLE Properties

Average information matrix : $\bar{J}_N(\theta) = -\mathbb{E} \left[\frac{1}{N} \frac{\partial^2 \log L(\theta)}{\partial \theta \partial \theta'} \right]$

Limiting information matrix: $J(\theta) \equiv \lim_{N \rightarrow \infty} \bar{J}_N(\theta)$

MLE, $\hat{\theta}$, is

- ▶ Consistent
- ▶ Asymptotically normal since $\sqrt{N}(\hat{\theta} - \theta) \rightarrow N(0, [J(\theta)]^{-1})$.
- ▶ Asymptotically efficient (Cramer - Rao lower bound).
- ▶ Invariant (continuous function theorem: MLE of $g(\theta)$ for any $g(\hat{\theta})$).
- ▶ $Var[S_i(\theta)] = \mathbb{E}[S_i(\theta)S_i(\theta)'] = J_i(\theta)$.

Can be estimated outer product of gradients (G)

$$\hat{V}_G = \left[\frac{1}{N} \sum_{i=1}^N S_i(\hat{\theta}) S_i(\hat{\theta})' \right]^{-1} \quad \text{or Hessian} \quad \hat{V}_H = \left[-\frac{1}{N} \sum_{i=1}^N \frac{\partial^2 \log L_i(\theta)}{\partial \theta \partial \theta'} \Big|_{\hat{\theta}} \right]^{-1}$$

Maximum Likelihood Estimation

- Introduction
- MLE Properties
- The Three Classical Tests of MLE

- ▶ Approximate $Var[h(\hat{\theta})] = G(\theta)' Var[\hat{\theta}]G(\theta)$ where $G(\theta) = \frac{\partial h(\theta)'}{\partial \theta}$.
- ▶ Test Statistic
 $\xi_w = Nh(\hat{\theta})'[G(\theta)'[J(\theta)]^{-1}G(\theta)]^{-1}h(\hat{\theta}), \xi_w \sim_a \chi^2(d)$.
- ▶ Estimate $[J(\theta)]^{-1}$ by \hat{V}_H or \hat{V}_G evaluated at $\hat{\theta}$, evaluate $G(\theta)$ at $\hat{\theta}$.
- ▶ Shortcoming: Wald test not invariant to how restrictions (linear/non-linear) are formulated.
- ▶ Overall question: How close is $h(\hat{\theta})$ to zero since $h(\tilde{\theta}) = 0$?

Alternative Computation

Alternative for ξ_{LM}

- ▶ Supplementary regression $\tilde{u} \sim x$
- ▶ $RSS = N\hat{\sigma}^2$.
- ▶ $TSS = N\tilde{\sigma}^2$

$$\Rightarrow R_u^2 = 1 - \frac{\hat{\sigma}^2}{\tilde{\sigma}^2}, \quad \xi_{LM} = NR_u^2$$
